

Course project

Select a (somewhat common) problem around which you will create a fictional customer. The customer obviously needs a stylish website, so produce a personal, theme-based, association or company website using a text editor/IDE that utilizes current web design standards (HTML5, CSS3). The project may be done in pairs. In addition to the website, you must write a reflective web report on the work.

The site should consist of, for example, 4 pages (no single page app) and it should contain real text and not "[Lorem Ipsum ...](#)".

The report should be in the form of a web report on one of the pages of your site. **Not a pdf, not a docx**, but nicely structured with p tags, h1 tags, etc.

The aim of the project is to learn the basics of HTML, learn how to use available tools, understand the basic principles of planning a good layout, good images and text, and be able to search the Internet and find ideas and material for web pages. Remember that a lot of material is copyrighted and therefore cannot be used on your pages.

Requirements:

1. The plan, the specification and scope 15p

Web designers face the challenge of selling a website to a customer before the site has been created. A skilled salesperson [can sell a pint of air](#), but if you and the customer have not agreed on clear specifications, the customer can always demand more and the project will never be completed.

What is the title of the site, who is the target audience, what is the customer's starting point (e.g., Instagram already exists), what is the purpose of the site, and how and when have you met the specifications?

Customers often lack knowledge of web development, so consider whether it would be useful to share some background or theory about web design and its working methods (e.g., why the customer cannot change the text on the site themselves after it is finished). Find out about some web development working methods that can facilitate development and communication with the customer and explain them to the customer in the specifications.

Also define responsiveness; the site should work on a mobile phone, tablet, and computer, right? What about 4K or 8K screens, what about older smartphones, does your site need to be displayed on a smartwatch? Plan responsiveness according to the customer group and inform the customer of any limitations.

You share your specifications well in advance of the presentations, and what you have achieved at the end is measured against the specification. Half of the work (at least!)

involved in a real web development project is careful specification. Then it's just a matter of implementation.

Consider the content and pages of the website. Draw (using Paint, Krita, or draw.io) a schematic diagram (a few boxes with text) of what the pages will contain and how to navigate between them (using arrows). Can all information be accessed from the home page, or are there multiple menus? Turn this diagram into a map of your entire website (Site Map) and place it somewhere on your website and in your web report. Can all information be accessed from the home page, or are there several menus?

Then sketch out images of the layouts and designs you will use on your website. Where should the logo, company name, page headings of different levels, menus, images, lists, texts, and links be placed? Should there be something common to all pages? Does the layout look the same on the main page and the other pages? Choose a color scheme for the website and consider color harmony:

[Color Matcher provides color tones, sliders for lightness and saturation.](#)

[All in one tool color.space is good for gradients, for example.](#)

Choose a font or typeface, as it is actually called, and consider what people think fonts express. [Google Fonts](#) [Google Design pages](#)

Attach images of the layout, color, font, and image selection to your specification. Keep in mind that this is what you are selling to the customer before you start developing. Things don't always turn out as planned, but if you don't plan at all, the end result will not be well thought out and will rarely meet the customer's expectations.

2. The structure, style and responsiveness 15p

Build the home page (index.html) for your website and follow current HTML5 guidelines; h1 on each page, block and inline tags, use <section>, <nav>, <article>, <header> and <footer> or <div> to create a neat layout on the pages. All pages should have a title, heading, text, and links.

Do not store images in larger formats than they are presented. Use at least one “drawn” image or icon in png or gif format with a transparent background, e.g., for your logo. Make sure that no style, layout, or formatting is controlled from html.

Create one or more Cascading Style Sheet (CSS) pages that describe your layout and the design you want for your page. Then link all your pages to the CSS file to achieve a consistent style. If you want one page to look slightly different from another, you can give it a separate CSS file that is loaded immediately after the style file that applies to all sites.

Use selectors and classes for the tags you have used (p, h1, h2, h3, p, body, etc.). Control fonts, colors, decoration, and backgrounds from CSS. Padding and margin allow you to insert empty spaces.

The navigation on the site should be clear and logical. Build a responsive menu that also works on mobile devices. Also keep in mind that users often want to go back or to the home page. Links should be colored when the mouse is hovered over them. Do this by using pseudo-classes for the a-selector in the CSS file. There should also be at least one link from an image, icon, or symbol.

YOUR WEBSITE

IS | THIS | YOUR | WEBSITE

This is the bit where you talk about how unique you are as
a business and that you're different to all of your competitors.
Your website looks the same though.

Always

You could have four columns here but you won't. You'll have three, like everyone else.

Three

Have a cog icon above one of these columns if you're really feeling especially creative.

Columns

The perfect place to talk about your services. Because co-incidentally, you have three of them.

© If someone did own the copyright to this layout, if that were even possible, they'd be rich!

Many websites use grids, flexboxes, and floats to create a responsive and attractive layout for web components. Use grids, flexboxes, and floats to place `<header>`, `<footer>`, and `<section>` elements in logical locations on the site. Work according to the mobile first principle, where we think out the patterns based on mobile devices, then tablets and desktops. However, don't think that mobile first means desktop last. If we look at device usage, tablets are "least important," but since tablets have the same screen sizes as ultrabooks, at least three breakpoints are probably necessary for the design.

3. Media, animations, content and scripts - 15p

We don't know JavaScript yet, but we know HTML! Build a simple gallery using an iframe. Remember not to store images in larger formats than they are presented in, and create thumbnails for the gallery to avoid slow loading times and reduce the load on the server.

Present one or more featured images on any page of your site. Use the HTML5 standard picture tag and create three images for different devices. Crop the image differently for different types of screens; a 16:9 image does not always fit on the screen of an iPhone X in portrait mode. We will learn more about data visualization in later courses, but as a webmaster, it is still important that you are familiar with two vector formats for the web, namely html5canvas and svg. Draw an image using either (or both?).

Record a video clip of something interesting. Think about the format. If your site will mainly be used on mobile devices, it may be okay to film in portrait mode, otherwise record the video in landscape mode [like an intellectual](#). Remember that the video should be in a format suitable for the web (not 4k 60fps). Also record an audio file, and include both the audio file and the video in a suitable place on your site.

Almost all sites use content from external service providers, such as Google Maps. Build in a map showing a location (think "Here you will find our office/store") using OpenStreetMaps.

Animate any part of the page using CSS3 animation. Add some keyframes that define the animation. (From and to are not enough for full points.)

4. Validation - 10p

Check that the pages you have built really do comply with the standard by validating them with <http://validator.w3.org/> and do the same for the CSS files with <http://jigsaw.w3.org/css-validator/>

5. Web report - 10p

Comment on and reflect on all aspects of this project and how the work has progressed in an HTML-based web report that is one of your web pages. What problems did you encounter? What was easy and what was fun? Also report how much time it took you.

In terms of content, I am looking for comments on how you chose to solve the tasks, which ones were difficult/easy, interesting/boring. What do you think you have learned during the course, what did you think was good/bad or fun/boring about the course, any requests for next year's course? Comments on what you would like to receive extra points for, thoughts on the design, etc. are also welcome. In terms of length, about one page of text is sufficient, as there are quite a few of you! Write something interesting, this thing is worth 10 points ;)

Bonus points - 10p

Smart implementations, clever ideas, or extra-stylish designs are all examples of opportunities to earn extra points. For example, stylish flexboxes could be an idea? Commitment should be rewarded, and an easy way to encourage you to go the extra mile is to award 10 points for innovation.

Grading:

Highly commendable (5) is given to an interesting, imaginative website with excellent structure, style, layout, content, and material which is self-produced. All participants in the

course should publish their pages on the web and submit the address of the website via itslearning.
